Setup Guide: DocExtract Pro

Invoice to Excel / Tally automation. Follow these steps in order.

1. What you need

- A computer or server with at least 4 GB RAM, and **one** of:
  - **Docker** (Windows: Docker Desktop. Linux: `curl -fsSL https://get.docker.com | sh`), or
  - **Python 3.11** (https://www.python.org/downloads/release/python-3119/, tick "Add python.exe to PATH") if you prefer not to use Docker.
- The project folder (unzip it, or `git clone https://github.com/AdityaWagh06/Document-to-Excel.git`).
- An **AI key**: OpenAI (https://platform.openai.com/api-keys, billing required) or free Google Gemini (https://aistudio.google.com/apikey).
- Only for internet access or WhatsApp: a **domain name**.
- Optional: TallyPrime with XML server on (port 9000), Meta WhatsApp Business app.

2. Configure

In the project folder, copy `.env.example` to `.env` and fill in:

Setting	Value
`SECRET_KEY`	Random text: `python -c "import secrets; print(secrets.token_hex(32))"`
`APP_ADMIN_USERNAME` / `APP_ADMIN_PASSWORD`	Your login (password 12+ characters)
`OPENAI_API_KEY` (or `GEMINI_API_KEY`)	Your AI key
`WHATSAPP_APP_SECRET` / `WHATSAPP_VERIFY_TOKEN`	Meta values, or any two random strings if WhatsApp is not used
`SESSION_COOKIE_SECURE`	`true` with HTTPS, `false` for plain `http://` on an office network
`PERMITTED_TALLY_URL` (optional)	Tally on the same PC: `http://localhost:9000` (Option A) or `http://host.docker.internal:9000` (Option B)

3. Start (choose one)

Option A: Windows without Docker (simplest). Double-click `start-windows.bat`. The first run installs everything (10 to 30 minutes); later runs start in seconds. Open **http://localhost:5000** and log in. Linux/macOS: `bash start-linux.sh`.

Option B: Docker.

```
docker compose up -d --build
```

Wait until `docker compose ps` shows both services **healthy** (first time 10 to 20 minutes). Open **http://localhost:8080** and log in.

Other office computers: with Option A set `HOST=0.0.0.0` and `SESSION_COOKIE_SECURE=false` in `.env`, then open `http://<this-pc-ip>:5000`. With Option B open `http://<this-pc-ip>:8080`.

4. Deploy online (optional)

1. Get a Linux server (4 GB RAM) and point your domain to its IP.
2. Do steps 1 to 3 (Option B) on the server, with `HTTP_BIND=127.0.0.1` and `TRUSTED_PROXIES_COUNT=2` in `.env`.
3. Install Caddy (https://caddyserver.com/docs/install) and put this in `/etc/caddy/Caddyfile`:

```
yourdomain.com {
    reverse_proxy 127.0.0.1:8080
}
```

4. Run `sudo systemctl reload caddy`. Open `https://yourdomain.com` (HTTPS is automatic).
5. WhatsApp: in the Meta dashboard set the webhook to `https://yourdomain.com/api/v1/whatsapp/webhook` with your verify token.

5. Keep it running

- Update: replace the folder (or `git pull`), then `start-windows.bat rebuild` (Option A) or `docker compose up -d --build` (Option B)
- Logs: the start window (Option A) or `docker compose logs backend` (Option B)
- Back up the database daily: see "Database, migrations and backups" in `README.md`.
